

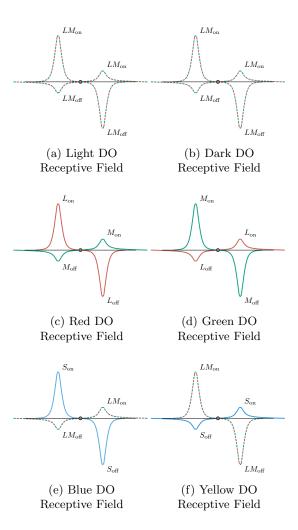

Figure 1: Diagram of Opponent Processing of Receptive Fields workflow. The L, M, and S channels are convoluted with center and surround gaussians and then combined to build opponent colors, here exemplified by single-opponent cell receptive fields.

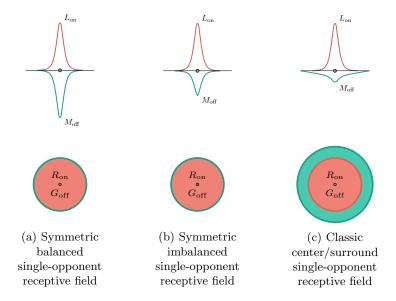

Figure 3: Examples of various possible single-opponent receptive field configurations, many others could be designed. All function to describe color properties of surfaces, though their response patterns to similar stimuli vary slightly.

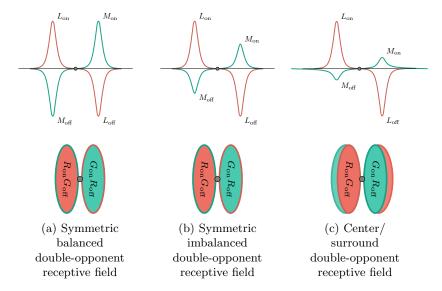

Figure 4: Examples of various possible double-opponent receptive field configurations, many others could be designed. All function to describe color properties of borders, though their response patterns to similar stimuli vary slightly.

(a) Vertical R vs. G double-opponent cell receptive fields.

(b) Vertical G vs. R double-opponent cell receptive fields.

(c) Diagonal R vs. G double-opponent cell receptive fields.

(d) Diagonal G vs. R double-opponent cell receptive fields.

(e) Horizontal R vs. G double-opponent cell receptive fields.

(f) Horizontal G vs. R double-opponent cell receptive fields.

(g) Diagonal R vs. G double-opponent cell receptive fields.

(h) Diagonal R vs. G double-opponent cell receptive fields.

Figure 5: Schematic of orientation selectivity in double-opponent receptive field configurations. Any single double-opponent neuron only has one receptive field hard wired into it. By having collections of neurons, each selective to a different orientation at the same retinotopic location, we obtain a degree of rotation invariance.

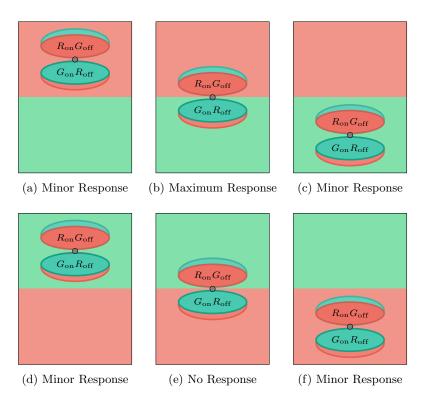

Figure 6: A double-opponent cell selective to horizontally oriented borders with red above and green below; only responsive to that particular stimulus. In Figure (b), the neuron is presented with its ideal stimulus: its  $L_{\rm on}$  and  $M_{\rm on}$  receptive fields are fully activated while its  $L_{\rm off}$  and  $M_{\rm off}$  receptive fields are completely unactivated. Figure (e) presents the neuron with the exact opposite stimulus, neither its  $L_{\rm on}$  nor  $M_{\rm on}$  receptive fields are activate at all, and both its  $L_{\rm off}$  and  $M_{\rm off}$  receptive fields are fully activated, ensuring no response possible from the cell. While its  $L_{\rm on}$  receptive field might be strongly stimulated in (a) and (f), it's  $L_{\rm off}$  receptive field cancels it out. Similarly, in (c) and (d) its  $M_{\rm off}$  receptive field is stimulated but cancelled out by activity in its  $M_{\rm off}$  receptive field.

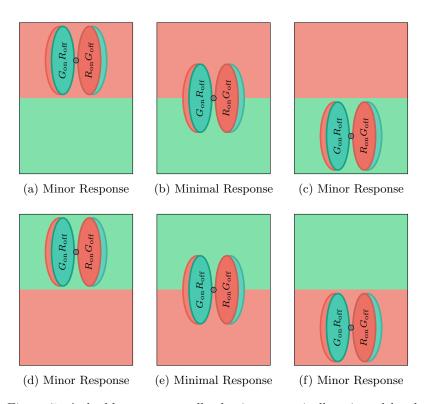

Figure 7: A double-opponent cell selective to vertically oriented borders with red to the right and green on the left; completely unresponsive to a horizontal border. While its  $L_{\rm on}$  receptive field might be strongly stimulated in (a) and (f), it's  $L_{\rm off}$  receptive field cancels it out. Similarly, in (c) and (d) its  $M_{\rm on}$  receptive field is stimulated but cancelled out by activity in its  $M_{\rm off}$  receptive field. In (b) and (e) both of its  $L_{\rm on}$  and  $M_{\rm on}$  receptive fields are moderately activated, but again, cancelled out by activation in its  $L_{\rm off}$  and  $M_{\rm off}$  receptive fields, respectively.
